

Specifications And Constraints

You must:

- Implement POST / Anmeldung: accept owner and dog data, calculate the tax, and save everything.
- The chip number is a mandatory field - if it is missing, respond with HTTP 400.
- Implement POST / Ummeldung: handle the case where a transfer happens from one tenant to another, re-assess according to the receiving tenant's regulations, mark the originating case as deregistered, and log the transfer in a tamper-proof manner.

You may:

- Choose any tech stack - framework, language, database library: everything is your decision.
- Build a UI - it is welcome and recommended but not mandatory. The evaluation is based on a working API.
- Use if/else statements for tax calculation - no complex rule engine is required.
- Implement tenant separation physically (separate databases/schemas) or logically (tenant_id column)
- Bonus: Generate a PDF notice, perform duplicate checks for the chip number within a tenant.

You may not:

- Use paid cloud services (no AWS, Azure, SAP BTP, or similar).
- Completely delete data from the originating tenant during transfer - for auditing reasons, the case must remain and be marked as deregistered.

Submission:

1. Working code: the API starts with one command
2. Live demo: demonstrate POST / Anmeldung and POST / Ummeldung. Show how data flows between tenants and how the log looks.
3. One slide or whiteboard sketch: Which two regulations did you use? How do you identify the tenant?

If you need help with anything else related to this task, feel free to ask! :)
